

# Integrated 16-Channel LED Drivers with Switch-Mode Boost and SEPIC Controller

## ABSOLUTE MAXIMUM RATINGS

V <sub>CC</sub> to AGND	-0.3V to +30V	OUT0–OUT15 Sink Current	60mA
Current into V <sub>CC</sub> (V <sub>CC</sub> > 24V)	30mA	Total PGND Current (1s pulse time)	960mA
V <sub>+</sub> to PGND	-0.3V to +6V	Continuous Power Dissipation (T <sub>A</sub> = +70°C)	
OUT to AGND	-0.3V to (V <sub>CC</sub> + 0.3V)	38-Pin TQFN (derate 35.7mW/°C* above +70°C)	2857mW
OUT Current (10μs duration)	±1A	Operating Temperature Range	-40°C to +125°C
FB, COMP, CS, RTCT, REF to AGND	-0.3V to +6V	Junction Temperature	+150°C
COMP Sink Current	10mA	Storage Temperature Range	-65°C to +150°C
OUT0–OUT15 to PGND	-0.3V to +40V	Lead Temperature (soldering, 10s)	+300°C
DIN, CLK, LE, OE, SET to PGND	-0.3V to (V <sub>+</sub> + 0.3V)		
DOUT Current	±10mA		

\*Per JEDEC51 Standard (Multilayer Board).

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ELECTRICAL CHARACTERISTICS (PWM CONTROLLER)

(V<sub>CC</sub> = +15V, V<sub>+</sub> = +3V to +5.5V referenced to PGND, R<sub>T</sub> = 10kΩ, C<sub>T</sub> = 3.3nF, REF = open, COMP = open, C<sub>REF</sub> = 0.1μF, V<sub>FB</sub> = 2V, CS = AGND, AGND = PGND = 0V; all voltages are measured with respect to AGND, unless otherwise noted. T<sub>J</sub> = T<sub>A</sub> = -40°C to +125°C, unless otherwise noted. Typical values are at T<sub>A</sub> = +25°C.) (Note 1)

## Pin Description

PIN	NAME	FUNCTION
1, 31, 32, 36, 38	N.C.	No Connection. Not internally connected. Leave unconnected.
2	FB	Error-Amplifier Inverting Input
3	COMP	Error-Amplifier Output
4–11	OUT8–OUT15	LED Driver Outputs. OUT8–OUT15 are open-drain, constant-current-sinking outputs rated for 36V.
12	$\overline{OE}$	Active-Low, Output Enable Input. Drive $\overline{OE}$ low to PGND to enable the OUT0–OUT15. Drive $\overline{OE}$ high to disable OUT0–OUT15.
13	DOUT	Serial-Data Output. Data is clocked out of the 16-bit internal shift register to DOUT on CLK's rising edge.
14	SET	LED Current Setting. Connect R <sub>SET</sub> from SET to PGND to set the LED current.
15	V+	LED Driver Positive Supply Voltage. Bypass V+ to PGND with a 0.1μF ceramic capacitor.
16, 17	PGND	Power Ground
18	DIN	Serial-Data Input. Data is loaded into the internal 16-bit shift register on CLK's rising edge.
19	CLK	Serial-Clock Input
20	LE	Latch-Enable Input. Data is loaded transparently from the internal shift register(s) to the output latch(es) while LE is high. Data is latched into the output latch(es) on LE's falling edge, and retained while LE is low.
21–28	OUT0–OUT7	LED Driver Outputs. OUT0–OUT7 are open-drain, constant-current-sinking outputs rated for 36V.
29	RTCT	PWM Controller Timing Resistor/Capacitor Connection. A resistor R <sub>T</sub> from RTCT to REF and a capacitor C <sub>T</sub> from RTCT to AGND set the oscillator frequency.
30	CS	PWM Controller Current-Sense Input
33	AGND	Analog Ground
34	OUT	MOSFET Driver Output OUT. Connects to the gate of the external n-channel MOSFET.
35	V <sub>CC</sub>	Power-Supply Input. Bypass V <sub>CC</sub> to AGND with a 0.1μF ceramic capacitor or a parallel combination of a 0.1μF and a higher value ceramic capacitor.
37	REF	5V Reference Output. Bypass REF to AGND with a 0.1μF ceramic capacitor.
—	EP	Exposed Paddle. Connect to the ground plane for improved power dissipation. Do not use as the only ground connection.

## Detailed Description

The MAX16809/MAX16810 LED drivers include an internal switch-mode controller that can be used as boost or buck-boost (SEPIC) converters to generate the voltage necessary to drive the multiple strings of LEDs. These devices incorporate an integrated low-side driver, a programmable oscillator (20kHz to 1MHz), an error amplifier, a low-voltage (300mV) current sense for higher efficiency, and a 5V reference to power up external circuitry (see Figures 1a, 1b, and 1c).

The MAX16809/MAX16810 LED drivers include a 4-wire serial interface and a current-mode PWM controller to generate the necessary voltage for driving 16 open-drain, constant-current-sinking output ports. The drivers

use current-sensing feedback circuitry (not simple current mirrors) to ensure very small current variations over the full allowed range of output voltage (see the *Typical Operating Characteristics*). The 4-wire serial interface comprises a 16-bit shift register and a 16-bit transparent latch. The shift register is written through a clock input, CLK, and a data input, DIN, and the data propagates to a data output, DOUT. The data output allows multiple drivers to be cascaded and operated together. The contents of the 16-bit shift register are loaded into the transparent latch through a latch-enable input, LE. The latch is transparent to the shift register outputs when high and latches the current state on the falling edge of LE. Each driver output is an open-drain, constant-current sink that should be connected to the

# Integrated 16-Channel LED Drivers with Switch-Mode Boost and SEPIC Controller

cathode of a string of LEDs connected in series. The constant-current capability is up to 55mA per output, set for all 16 outputs by an external resistor,  $R_{SET}$ . The devices can operate in a stand-alone mode (see the *Typical Operating Circuits*).

The MAX16810 includes circuitry that automatically detects open-circuit LEDs. Fault status is loaded into the serial-interface shift register when LE goes high and is

automatically shifted out on DOUT when the next data transmission is shifted in. The MAX16810 also features a watchdog that monitors activity on the CLK, DIN, and LE inputs (see the *Watchdog (MAX16810)* section). The number of channels can be expanded by using the MAX6970 and MAX6971 family in conjunction with the MAX16809 and MAX16810.

## Switch-Mode Controller

### Current-Mode Control Loop

The advantages of current-mode control over voltage-mode control are twofold. First, there is the feed-forward characteristic brought on by the controller's ability to adjust for variations in the input voltage on a cycle-by-cycle basis. Second, the stability requirements of the current-mode controller are reduced to that of a single-pole system unlike the double pole in the voltage-mode control scheme. The MAX16809/MAX16810 use a current-mode control loop where the output of the error amplifier is compared to the current-sense voltage ( $V_{CS}$ ). When the current-sense signal is lower than the inverting input of the CPWM comparator, the output of the comparator is low and the switch is turned on at each clock pulse. When the current-sense signal is higher than the inverting input of the CPWM comparator, the output is high and the switch is turned off.

### Undervoltage Lockout (UVLO)

The turn-on supply voltage for the MAX16809/MAX16810 is 8.4V (typ). Once  $V_{CC}$  reaches 8.4V, the reference powers up. There is a 0.8V of hysteresis from the turn-on voltage to the UVLO threshold. Once  $V_{CC}$  reaches 8.4V, the MAX16809/MAX16810 operate with  $V_{CC}$  down to 7.6V. Once  $V_{CC}$  goes below 7.6V (typ), the device is in UVLO. When in UVLO, the quiescent supply current into  $V_{CC}$  falls back to 32 $\mu$ A (typ), and OUT and REF are pulled low.

### MOSFET Driver

OUT drives an external n-channel MOSFET and swings from AGND to  $V_{CC}$ . Ensure that  $V_{CC}$  remains below the absolute maximum  $V_{GS}$  rating of the external MOSFET.

OUT is a push-pull output with the on-resistance of the pMOS typically 3.5 $\Omega$  and the on-resistance of the nMOS typically 4.5 $\Omega$ . The driver can source 2A and sink 1A typically. This allows for the MAX16809/MAX16810 to quickly turn on and off high gate-charge MOSFETs. Bypass  $V_{CC}$  with one or more 0.1 $\mu$ F ceramic capacitors to AGND, placed close to  $V_{CC}$ . The average current sourced to drive the external MOSFET depends on the total gate charge ( $Q_G$ ) and operating frequency of the converter. The power dissipation in the MAX16809/MAX16810 is a function of the average output drive current ( $I_{DRIVE}$ ). Use the following equation to calculate the power dissipation in the device due to  $I_{DRIVE}$ :

$$I_{DRIVE} = (Q_G \times f_{SW})$$

$$PD = (I_{DRIVE} + I_{CC}) \times V_{CC}$$

where  $I_{CC}$  is the operating supply current. See the *Typical Operating Characteristics* for the operating supply current at a given frequency.

### Error Amplifier

The MAX16809/MAX16810 include an internal error amplifier. The inverting input is at FB and the noninverting input is internally connected to a 2.5V reference. Set the output voltage using a resistive divider between output of the converter  $V_{OUT}$ , FB, and AGND. Use the following formula to set the output voltage:

$$V_{OUT} = \left(1 + \frac{R_1}{R_2}\right) \times V_{FB}$$

where  $V_{FB} = 2.5V$ .

### Oscillator

The oscillator frequency is programmable using an external capacitor and a resistor at RTCT (see  $R_T$  and  $C_T$  in the *Typical Operating Circuits*).  $R_T$  is connected from RTCT to the 5V reference (REF), and  $C_T$  is connected from RTCT to AGND. REF charges  $C_T$  through  $R_T$  until its voltage reaches 2.8V.  $C_T$  then discharges through an 8.3mA internal current sink until  $C_T$ 's voltage reaches 1.1V, at which time  $C_T$  is allowed to charge through  $R_T$  again. The oscillator's period is the sum of the charge and discharge times of  $C_T$ . Calculate the charge time as follows:

$$t_C = 0.57 \times R_T \times C_T$$

where  $t_C$  is in seconds,  $R_T$  in ohms ( $\Omega$ ), and  $C_T$  in Farads (F).

The discharge time is then:

$$t_D = (R_T \times C_T \times 1000) / [(4.88 \times R_T) - (1.8 \times 1000)]$$

where  $t_D$  is in seconds,  $R_T$  in ohms ( $\Omega$ ), and  $C_T$  in Farads (F).

# Integrated 16-Channel LED Drivers with Switch-Mode Boost and SEPIC Controller

MAX16809/MAX16810

The oscillator frequency is then:

$$f_{osc} = \frac{1}{(t_C + t_D)}$$

$$R_{CS} = \frac{V_{CS}}{I_{P-P}}$$

$I_{P-P}$  is the peak current that flows through the MOSFET. When the voltage produced by this current (through the current-sense resistor) exceeds the current-limit comparator threshold, the MOSFET driver (OUT) turns the switch off within 60ns. In most cases, a small RC filter is required to filter out the leading-edge spike on the sense waveform. Set the time constant of the RC filter at 50ns.

## Reference Output

REF is a 5V reference output that can source 20mA. Bypass REF to AGND with a 0.1µF capacitor.

## Current Limit

The MAX16809/MAX16810 include a fast current-limit comparator to terminate the ON cycle during an overload or a fault condition. The current-sense resistor,  $R_{CS}$ , connected between the source of the external MOSFET and AGND, sets the current limit. The CS input has a voltage trip level ( $V_{CS}$ ) of 0.3V. Use the following equation to calculate  $R_{CS}$ :

## Buck-Boost (SEPIC) Operation

Figure 2 shows a buck-boost application circuit using the MAX16809/MAX16810 in a stand-alone mode of operation. SEPIC topology is necessary when the total forward voltage of the LEDs in a string is such that  $V_{OUT}$  can be below or above  $V_{IN}$ .

Figure 2. Buck-Boost (SEPIC) Operation

# Integrated 16-Channel LED Drivers with Switch-Mode Boost and SEPIC Controller

## LED Driver

### 4-Wire Interface

The MAX16809/MAX16810 also operate in a stand-alone mode (see the *Typical Operating Circuits*). For use with a microcontroller, the MAX16809/MAX16810 feature a 4-wire serial interface using DIN, CLK, LE,  $\overline{OE}$  inputs and DOUT as a data output. This interface is used to write the LED channels' data to the MAX16809/MAX16810. The serial-interface data word length is 16 bits, D0–D15. See Figure 3.

The functions of the five interface pins are as follows:

DIN is the serial-data input, and must be stable when it is sampled on the rising edge of CLK. Data is shifted in MSB first. This means that data bit D15 is clocked in first, followed by 15 more data bits, finishing with the LSB, D0.

CLK is the serial-clock input that shifts data at DIN into the MAX16809/MAX16810's 16-bit shift register on its rising edge.

LE is the latch-enable input of the MAX16809/MAX16810 that transfers data from the 16-bit shift register to its 16-bit output latches (transparent latch). The data latches on the falling edge of LE (Figure 4). The fourth input ( $\overline{OE}$ ) provides output-enable control of the output drivers. When  $\overline{OE}$  is driven high, the outputs (OUT0–OUT15) are forced to high impedance without altering the contents of the output latches. Driving  $\overline{OE}$  low enables the outputs to follow the state of the output latches.  $\overline{OE}$  is independent of the serial interface operation. Data can be shifted into the serial-interface shift register and latched, regardless of the state of  $\overline{OE}$ . DOUT is the serial-data output that shifts data out from the MAX16809/MAX16810's 16-bit shift register on the rising edge of CLK. Data at DIN propagates through the shift register and appears at DOUT 16 clock cycles later. Table 1 shows the 4-wire serial-interface truth table.

**Table 1. 4-Wire Serial-Interface Truth Table**

SERIAL DATA INPUT DIN	CLOCK INPUT CLK	SHIFT REGISTER CONTENTS						LOAD INPUT LE	LATCH CONTENTS						BLANKING INPUT $\overline{OE}$	OUTPUT CONTENTS CURRENT AT OUT__					
		D0	D1	D2	...	Dn-1	Dn		D0	D1	D2	...	Dn-1	Dn		D0	D1	D2	...	Dn-1	Dn
H		H	R0	R1	...	Rn-2	Rn-1

Figure 3. 4-Wire Serial-Interface Timing Diagram

Figure 4. LE and CLK to OUT\_ \_ Timing

## Watchdog (MAX16810)

The MAX16810 includes a watchdog circuit that monitors the CLK, DIN, and LE inputs. If there is no transition on any one of these inputs for nominally 1s, the output latches are cleared and outputs OUT0–OUT15 go high impedance like the initial power-up condition. This turns off all LEDs connected to the outputs. The shift-register data does not change, just the output-latch data. When the watchdog triggers, the outputs remain off until the driver output latches are updated with data turning them on. Recovery is therefore automatic if the transmission failure is temporary because the MAX16810 does not lock up in the watchdog timeout state. The MAX16810 operates correctly when the serial interface is next activated, and the watchdog circuit is reset and starts monitoring the serial interface again. The watchdog function requires no software change to the application driving the MAX16810. The rise time for CLK, DIN, and LE should be less than 10 $\mu$ s.

# Integrated 16-Channel LED Drivers with Switch-Mode Boost and SEPIC Controller

## LED Fault Detection (MAX16810)

The MAX16810 includes circuitry that detects open-circuit LEDs automatically. An open-circuit fault occurs when an output is sinking current less than approximately 50% of the programmed current flows. Open circuits are checked just after the falling edge of  $\overline{OE}$ . The fault data is latched on the rising edge of LE and is shifted out when new LED data is loaded into the output latches from the shift register. If one or more output ports are detected with an open-circuit fault, the D14 and D13 bits of DOUT go high. If no open-circuit faults are detected, D14 and D13 are set to low. The data in the other 14 bit positions in DOUT are not altered. Fault status is shifted out on DOUT for the first two rising edges of the clock after the falling edge of LE (see Figure 5). LE is normally taken high after all 16 bits of new LED data have been clocked into the shift register(s), and then DOUT outputs data bit D15. A typical fault-detecting application tests all the shifted out data. Bits D0–D12 and D15 are checked against the originally transmitted data to check data-link integrity. Bits D13 and D14 are checked first to see that they contain the same data (validating the status), and second, whether faults are reported or not by the actual logic level.

Figure 5. Fault Timing

## Selecting External Component RSET to Set LED Output Current

The MAX16809/MAX16810 use an external resistor,  $R_{SET}$ , to set the LED current for outputs OUT0–OUT15. The minimum allowed value of  $R_{SET}$  is  $311\Omega$ , which sets the output currents to 55mA. The maximum allowed value of  $R_{SET}$  is  $5k\Omega$  ( $I_{OUT\_} = 3.6mA$ ) and maximum allowed capacitance at SET is 100pF.

Use the following formula to set the output current:

$$R_{SET} = \frac{17,100V}{I_{OUT\_}}$$

where  $I_{OUT\_}$  is the desired output current in milliamps and the value for  $R_{SET}$  is in ohms.

## Overtemperature Cutoff

The MAX16809/MAX16810 contain an internal temperature sensor that turns off all outputs when the die temperature exceeds  $+165^{\circ}C$ . The outputs are enabled again when the die temperature drops below  $+140^{\circ}C$ . Register contents are not affected, so when a driver is overdissipating, the external symptom is the load LEDs cycling on and off as the driver repeatedly overheats and cools, alternately turning itself off and then back on again.

## Stand-Alone Operation

In stand-alone operation, the MAX16809/MAX16810 does not use the 4-wire interface (see the *Typical Operating Circuits*). Connect DIN and LE to  $V+$  and provide at least 16 external clock pulses to CLK to enable 16 output ports. This startup pulse sequence can be provided either using an external clock or the PWM signal. The external clock can also be generated using the signal at RTCT and an external comparator.

# Integrated 16-Channel LED Drivers with Switch-Mode Boost and SEPIC Controller

## LED Dimming

### PWM Dimming

All the output channels can be dimmed simultaneously by applying a PWM signal (50Hz to 30kHz) to  $\overline{OE}$ . This allows for a wide range of dimming up to a 5000:1 ratio. Each channel can be independently turned on and off using a 4-wire serial interface. The dimming is proportional to the PWM duty cycle.

### LED Current Amplitude Adjustment

Using an analog or digital potentiometer as RSET allows for LED current amplitude adjustment and linear dimming.

### Computing Power Dissipation

Use the following equation to estimate the upper limit power dissipation (PD) for the MAX16809/MAX16810:

$$PD = DUTY \times \left[ (V_+ \times I_+) + \sum_{i=0}^{i=15} V_{OUTi} \times I_{OUTi} \right] + (V_{CC} \times I_{CC})$$

where:

$V_+$  = supply voltage

$I_+$  =  $V_+$  operating supply current

DUTY = PWM duty cycle applied to  $\overline{OE}$

$V_{OUTi}$  = MAX16809/MAX16810 port output voltage when driving load LED(s)

$I_{OUTi}$  = LED drive current programmed by RSET

PD = power dissipation

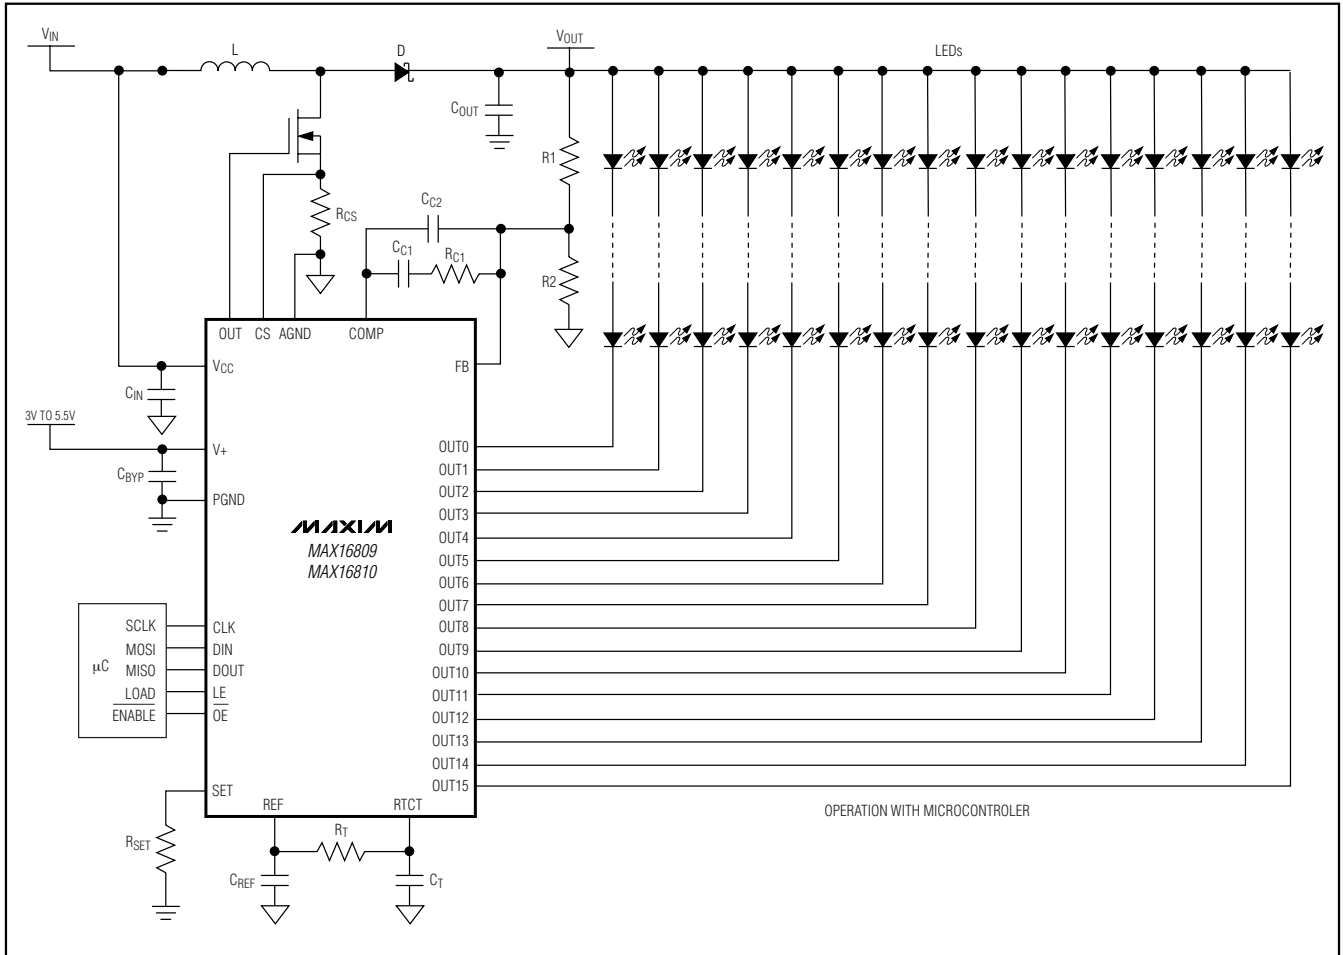

## PCB Layout Guidelines

Careful PCB layout is critical to achieve low switching losses and clean, stable operation. Use a multilayer board whenever possible for better noise immunity. Protect sensitive analog grounds by using a star ground configuration. Minimize ground noise by connecting AGND, PGND, the input bypass-capacitor ground lead, and the output-filter ground lead to a single point (star ground configuration). Also, minimize trace lengths to reduce stray capacitance, trace resistance, and radiated noise. The trace between the output voltage-divider and the FB pin must be kept short, as well as the trace between AGND and PGND.
