## Notes

1. With a load connected to the outputs the quiescent current will increase, the maximum value of this increase being equal to the DC output offset voltage divided by  $R_L$ .
2. The noise output voltage (RMS value) at  $f = 500\text{ kHz}$  is measured with  $R_S = 0\text{ }\Omega$  and  $B = 5\text{ kHz}$ .
3. The ripple rejection is measured with  $R_S = 0\text{ }\Omega$  and  $f = 100\text{ Hz}$  to  $10\text{ kHz}$ . The ripple voltage  $V_R$  of  $200\text{ mV}$  (RMS value) is applied to the positive supply rail.
4. The noise output voltage (RMS value) is measured with  $R_S = 5\text{ k}\Omega$  unweighted.
5. The DC volume control can be configured in several ways. Two possible circuits are shown in Figs 14 and 15. The circuits at the volume control pin will influence the switch-on and switch-off behaviour and the maximum voltage gain.

## FUNCTIONAL DESCRIPTION

The ILA7056B is a mono BTL output amplifier with DC volume control, designed for use in TV and monitor but is also suitable for battery-fed portable recorders and radios.

In conventional DC volume circuits the control or input stage is AC coupled to the output stage via external capacitors to keep the offset voltage low. In the ILA7056B the DC volume control stage is integrated into the input stage so that no coupling capacitors are required. With this configuration, a low offset voltage is still maintained and the minimum supply voltage remains low.

The BTL principle offers the following advantages:

- Lower peak value of the supply current
- The frequency of the ripple on the supply voltage is twice the signal frequency.

Consequently, a reduced power supply with smaller capacitors can be used which results in cost reductions. For portable applications there is a trend to decrease the supply voltage, resulting in a reduction of output power at conventional output stages. Using the BTL principle increases the output power.

The maximum gain of the amplifier is fixed at 40.5 dB. The DC volume control stage has a logarithmic control characteristic. Therefore, the total gain can be controlled from 40.5 dB to 33 dB. If the DC volume control voltage falls below 0.4 V, the device will switch to the mute mode.

The amplifier is short-circuit proof to ground,  $V_P$  and across the load. Also a thermal protection circuit is implemented. If the crystal temperature rises above +150 °C the gain will be reduced, thereby reducing the output power. Special attention is given to switch-on and switch-off clicks, low HF radiation and a good overall stability.

### Power dissipation

Assume  $V_P = 12\text{ V}$ ;  $R_L = 16\ \Omega$ .

The maximum sine wave dissipation is = 1.8 W.

The  $R_{th\ vj-a}$  of the package is 55 K/W.

Therefore  $T_{amb\ (max)} = 150 - 55 \times 1.8 = 51\ ^\circ\text{C}$ .
